# 1 Lecture 15: Inverting the Hilbert transform and ideal fluid flow

In this lecture we

- 1. Discuss how to invert a Hilbert transform
- 2. Use it to solve ideal fluid flow around a plate

# 1.1 Inverting the Hilbert transform

We now consider the problem of finding u such that

$$H_{[a,b]}u(x) = f(x)$$

for a < x < b. Note that this is an additive jump problem: if we write  $\phi(z) = \mathcal{C}u(z)$  then we want to solve

$$-i(\phi_{+}(x) + \phi_{-}(x)) = f(x)$$

where  $\phi$  satisfies the conditions of Plemelj (Analyticity off [a, b], weaker than pole singularities, decay at  $\infty$ ). If we can find such a  $\phi$ , Plemelj guarantees that u is recovered via

$$\phi_{+}(x) - \phi_{-}(x) = (\mathcal{C}^{+} - \mathcal{C}^{-})u(x) = u(x)$$

To tackle this we are going to reduce it to a subtractive problem. Writing

$$\kappa(z) = \frac{1}{\sqrt{z - a}\sqrt{z - b}}$$

which satisfies

$$\kappa_{+}(x) = i\sqrt{b-x}\sqrt{x-a} = -i\kappa_{-}(x)$$

Thus if we write

$$\phi(z) = \kappa(z)\psi(z)$$

for some new unkown  $\psi$  we have that

$$f(x) = -i(\phi_{+}(x) + \phi_{-}(x)) = -i(\frac{\psi_{+}(x)}{\kappa_{+}(x)} + \frac{\psi_{-}(x)}{\kappa_{-}(x)} = -i\frac{\psi_{+}(x) - \psi_{-}(x)}{\kappa_{+}(x)}$$

In other words, we want

$$\psi_{+}(x) - \psi_{-}(x) = -if(x)\kappa_{+}(x) = -f(x)\sqrt{b-x}\sqrt{x-a}$$

where we need  $\psi$  to be bounded (the decay in  $\kappa$  then ensures the decay in  $\phi$ ). Therefore by Plemelj we have for  $g(x) = f(x)\sqrt{b-x}\sqrt{x-a}$ 

$$\psi(z) = -\mathcal{C}g(z) + D$$

and hence for

$$u(x) = \phi_{+}(x) - \phi_{-}(x) = \psi_{+}(x)\kappa_{+}(x) - \psi_{-}(x)\kappa_{-}(x)$$

$$= -\frac{C^{+}g(x) + C^{-}g(x) + 2D}{\kappa_{+}(x)} = -\frac{i\mathcal{H}g(x) + 2D}{\kappa_{+}(x)}$$

$$= -\frac{\mathcal{H}_{[a,b]}[f\sqrt{b-\phi}\sqrt{\phi-a}](x) + 2D}{\sqrt{b-x}\sqrt{x-a}}$$

where  $\diamond$  denotes a dummy variable and D is arbitrary.

In practice we determine  $\mathcal{H}g(x)$  by first computing its Cauchy transform.

Example Let's try with f(x) = x on [-1, 1]. The first step is to compute the Cauchy transform of  $g(x) = x\sqrt{1-x^2}$ . Using the usual technique this gives

$$Cg(z) = \frac{z\sqrt{z-1}\sqrt{z+1} - z^2 + 1/2}{2i}$$

where we use the Laurent series

$$\sqrt{z-1}\sqrt{z+1} = z\sqrt{1-1/z}\sqrt{1+1/z}$$

$$= z(1+1/(2z)-1/(8z^2)+O(z^{-3})(1-1/(2z)-1/(8z^2)+O(z^{-2})$$

$$= z-\frac{1}{2z}+O(z^{-1})$$

Therefore

$$\mathcal{H}g(x) = -\mathrm{i}(\mathcal{C}^+ + \mathcal{C}^-)g(x) = -\frac{x\sqrt{x-1} + \sqrt{x+1} - x\sqrt{x-1} - \sqrt{x+1}}{2} + x^2 - 1/2$$
$$= x^2 - 1/2$$

Giving us

$$u(x) = -\frac{x^2 - 1/2 + 2D}{\sqrt{1 - x^2}}$$

Choosing D = -1/4 recovers the known solution  $\sqrt{1-x^2}$ .

# 1.2 Ideal fluid flow

Understanding branch cuts and Cauchy transforms allows us to systematically solve equations involving Laplace equation. A classic example is Ideal fluid flow. Consider the case of uniform flow with angle  $\theta$  around an infinitesimally small plate on [-1, 1]. We can model this as

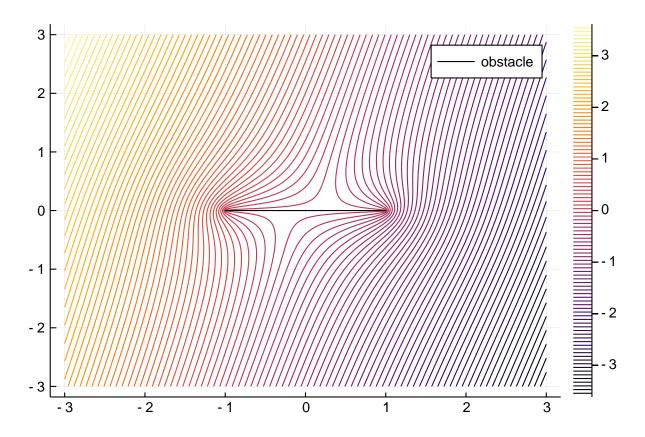

$$v(x, y) \sim y \cos \theta - x \sin \theta$$

$$v_{xx} + v_{yy} = 0$$

$$v(x, 0) = 0 \quad \text{for} \quad -1 < x < 1$$

Using the techniques we developed in the last few lectures, we obtain a nice, simple, closed form expression as the imaginary part of an analytic function:

```
using Plots, LinearAlgebra, ApproxFun, SingularIntegralEquations Cw = (\theta,z) \rightarrow -im*sin(\theta)*(sqrt(z-1)sqrt(z+1) - z) \varphi = (\theta,z) \rightarrow exp(-im*\theta)*z + Cw(\theta,z) u = (\theta,x,y) \rightarrow imag(\varphi(\theta, x + im*y)) xx = yy = range(-3; stop=3, length=500) contour(xx, yy, u.(1.3,xx',yy); nlevels = 100) plot!(Segment(-1.,1.); color=:black, label="obstacle")
```

We divide this task into stages:

- 1. Rephrasing as a complex-analytical problem: v(x,y) to  $\phi(z)$
- 2. Reduction to inverting a Hilbert transform:  $\phi(z)$  to w(x)
- 3. Calculating the inverse Hilbert transform: Finding w(x)

4. Calculating its Cauchy transform: w(x) to  $\phi(z)$ 

## 1.2.1 Real and imaginary parts of analytic functions satisfy Laplace's equation

The real and imaginary parts of an analytic function satisfy Laplace's equation: that is if  $\phi(z) = \phi(x + iy) = u(x, y) + iv(x, y)$  where u and v are the real/imaginary parts, then

$$u_{xx} + u_{yy} = 0$$
$$v_{xx} + v_{yy} = 0$$
$$= 0$$

To see this, note that the complex-derivative of  $\phi(z)$  can be written in terms of two different partial derivatives:

$$\phi'(z) = \lim_{h \to 0} \frac{\phi(z+h) - \phi(z)}{h} = \lim_{h \to 0} \frac{u(x+h,y) - u(x,y) + \mathrm{i}(v(x+h,y) - v(x,y))}{h} = u_x + \mathrm{i}v_x$$

$$\phi'(z) = \lim_{h \to 0} \frac{\phi(z+\mathrm{i}h) - \phi(z)}{\mathrm{i}h} = \lim_{h \to 0} \frac{u(x,y+h) - u(x,y) + \mathrm{i}(v(x,y+h) - v(x,y))}{\mathrm{i}h} = -\mathrm{i}u_y + v_y$$

Taking a second derivative we get two equations:

$$\phi''(z) = u_{xx} + iv_{xx} = -u_{xx} - iv_{yy}$$

which implies  $u_{xx} + u_{yy} = 0$  and  $v_{xx} + v_{yy} = 0$ .

### 1.2.2 2. Reduce PDE to the Hilbert transform of an unknown function

Therefore we can rewrite the ideal fluid flow equation as a problem of calculating  $\phi(z) = u(x,y) + iv(x,y)$  whose imaginary part is the solution too the ideal fluid flow PDE (we don't use the real part u). That is, we want to find analytic  $\phi(z)$  that satisfies

$$\phi(z) \sim e^{-i\theta}z$$
  
 $\Im \phi(x) = 0$  for  $-1 < x < 1$ 

Write

$$\phi(z) = e^{-i\theta}z + c + C_{[-1,1]}w(z)$$

for an as-of-yet unknown function w and C an unknown constant, we have (assuming w is real) that

$$0 = \Im \phi(x) = -x \sin \theta + \Im c + \Im C_{[-1,1]}^+ w(x) = -x \sin \theta + \Im c + \frac{1}{2} \mathcal{H} w(x)$$

In this example, we can take c = 0. Therefore, we want to solve

$$\mathcal{H}w(x) = 2x\sin\theta$$

for w.

## 1.2.3 3. Calculating the inverse Hilbert transform

We now plug the problem into the inverse Hilbert transform formula:

$$w(x) = \frac{-1}{\sqrt{1-x^2}} \mathcal{H}[f\sqrt{1-\diamond^2}](x) + \frac{D}{\sqrt{1-x^2}}$$

where  $f(x) = 2x \sin \theta$ . Now that

Similar to last lecture, we find

$$C[\diamond \sqrt{1-\diamond^2}](z) = \frac{z\sqrt{z-1}\sqrt{z+1}-z^2+1/2}{2i}$$

and therefore

$$\mathcal{H}[\diamond\sqrt{1-\diamond^2}](x) = -\mathrm{i}(\mathcal{C}^+ + \mathcal{C}^-)[\diamond\sqrt{1-\diamond^2}](x) = x^2 - \frac{1}{2}$$

Thus (relabeling D) we have

$$w(x) = 2\sin\theta \frac{x^2 - D}{\sqrt{1 - x^2}}$$

Demonstration Here we see that this gives us the right Hilbert transform:

D = randn()

 $\theta = 0.1$ 

x = Fun()

 $w = 2\sin(\theta) * (D-x^2)/sqrt(1-x^2)$ 

-hilbert(w,0.2) ,  $2\sin(\theta)*0.2$  # Minus in front of w to fix normalisation

(0.03993336665873126, 0.03993336665873126)

D

is arbitrary, but from physical principles we know that we don't want the solution to blow up. If w blows up then so does its Cauchy transform. Therefore, we choose D = -1 so that

$$w(x) = 2\sin\theta\sqrt{1 - x^2}$$

### 1.2.4 4. Calculating its Cauchy transform

Now recall

$$C\left[\sqrt{1-\diamond^2}\right](z) = \frac{\sqrt{z-1}\sqrt{z+1}-z}{2i}$$

Therefore,  $w(x) = 2\sin\theta\sqrt{1-x^2}$ , implies

$$Cw(z) = -i\sin\theta(\sqrt{z-1}\sqrt{z+1}-z)$$

which means

$$\phi(z) = e^{-i\theta}z - i\sin\theta(\sqrt{z-1}\sqrt{z+1} - z).$$

# 1.3 Numerical example of two intervals

We note that for obstacles on the real line, represented by a contour  $\Gamma$ , the problem of ideal fluid flow around  $\Gamma$  is still reducible to solving the singular integral equation

$$\mathcal{H}_{\Gamma}f(x) = 2x\sin\theta$$

Even when not solvable exactly, one can solve it numerically:

```
a = 0.3 \theta = 1.3 \Gamma = Segment(-1,-a) \cup Segment(a, 1) \Gamma = Segment(-1,-a) \cup Segment(a, 1) \Gamma = Fun(\Gamma) sp = PiecewiseSpace(JacobiWeight.(0.5,0.5,components(\Gamma))...) \Gamma = Hilbert(sp) \Gamma = Fun(\Gamma = Fun(\Gamma
```
